PREFACE

This report is prepared under guidance contained in the Recommended Guidelines for Safety Inspection of Dams, for Phase I Investigations. Copies of these guidelines may be obtained from the Office of Chief of Engineers, Washington, D.C. 20314. The purpose of a Phase I investigation is to identify expeditiously those dams which may pose hazards to human life or property. The assessment of the general condition of the dam is based upon available data and visual inspections. Detailed investigation, and analyses involving topographic mapping, subsurface investigations, testing, and detailed computational evaluations are beyond the scope of a Phase I investigation; however, the investigation is intended to identify any need for such studies.

In reviewing this report, it should be realized that the reported condition of the dam is based on observations of field conditions at the time of inspection along with data available to the inspection team. In cases where the reservoir was lowered or drained prior to inspection, such action, while improving the stability and safety of the dam, removes the normal load on the structure and may obscure certain conditions which might otherwise be detectable if inspected under the normal operating environment of the structure.

It is important to note that the condition of a dam depends on numerous and constantly changing internal and external conditions, and is evolutionary in nature. It would be incorrect to assume that the present condition of the dam will continue to represent the condition of the dam at some point in the future. Only through frequent inspections can unsafe conditions be detected and only through continued care and maintenance can these conditions be prevented or corrected.

Phase I inspections are not intended to provide detailed hydrologic and hydraulic analyses. In accordance with the established Guidelines, the spillway design flood is based on the estimated "Probable Maximum Flood" for the region (greatest reasonably possible storm runoff), or fractions thereof. The spillway design flood provides a measure of relative spillway capacity and serves as an aid in determining the need for more detailed hydrologic and hydraulic studies, considering the size of the dam, its general condition and the downstream damage potential.

PHASE I INSPECTION REPORT

NATIONAL DAM INSPECTION PROGRAM

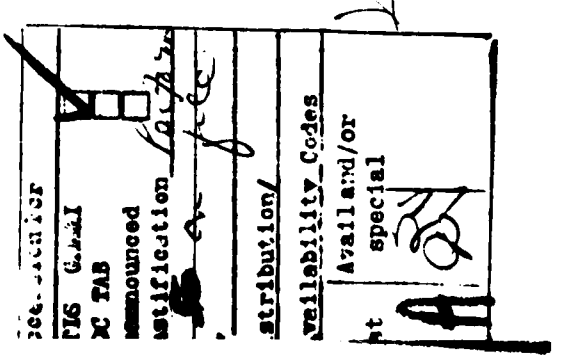
BRIEF ASSESSMENT OF GENERAL CONDITION

AND

RECOMMENDED ACTION

Name of Dam:	Meadow Run Dam NDI ID NO. PA-00555 DER ID No. 40-51
Size:	Small (15 feet high; 567 acre-ft)
Hazard Classification:	High
Owner:	Mrs. Eleanor Taylor 1360 Jack Road Monterey, California 93940 c/o Corresponding Agent Mr. Lee Sweinburg 589 Wyoming Ave. Wyoming, Pennsylvania 18644
State Located:	Pennsylvania
County Located:	Luzerne
Stream:	Meadow Run
Date of Inspection:	16 April 1980

Based on criteria established for these studies, Meadow Run Dam is judged to be unsafe, nonemergency, because the spillway capacity is seriously inadequate. The recommended Spillway Design Flood (SDF) for the size and hazard category of the dam varies between 1/2 of the



Probable Maximum Flood (PMF) and the PMF. Based on the criteria and the downstream conditions, the selected SDF is the PMF. Based on existing conditions, the spillway will pass about 13 percent of the PMF before overtopping of the dam occurs. Failure of the dam would increase the hazard to loss of life downstream. If the dam were raised to its design elevation, the spillway would pass about 35 percent of the PMF. The spillway capacity would still be rated as seriously inadequate. As a whole, the dam is judged to be in poor condition.

Because of the nature of its construction, the steep downstream slope, and cracks that have developed on the top of the embankment, the stability of the embankment is considered marginal.

There is no evidence to suggest that the emergency drawdown facility is operational. It is in poor condition. Maintenance at the dam is inadequate.

The following studies and remedial measures are recommended to be undertaken by the Owner, in approximate order of priority, immediately:

(1) Remove the steel I-beams lying near the spillway weir.

(2) Perform additional studies to more accurately ascertain the spillway capacity required for Meadow Run Dam as well as the nature and extent of measures required to provide adequate spillway capacity. The studies should also assess the need for an improved outlet channel for the existing spillway and the erosion potential at the spillway. Take appropriate action as required.

(3) Perform comprehensive investigations and studies as required to assess the structural stability for the dam. The investigations and studies should address conditions within the dam and foundation. Take appropriate action as required. These studies should also address the slope protection required to prevent erosion. The final top of dam elevation should be coordinated with the spillway study recommended above. Until the studies are complete and any necessary remedial action taken, the Owner should monitor the condition of the dam. If any changes occur, immediate remedial action should be taken.

(4) Provide whatever measures are necessary to make the outlet works operational. Once operational, it should be maintained and operated on a regular basis. Also provide an upstream closure facility for the outlet works and assess the need for a structure around the gate valve to protect it from freezing.

(5) Remove trees and brush growing on or near the embankment.

All investigations, studies, designs, and inspection of construction should be performed by a professional engineer experienced in the design and construction of dams. Tree removal should also be guided by a professional engineer.

In addition, the Owner should institute the following operational and maintenance procedures:

(1) Develop a detailed emergency operation and warning system for Meadow Run Dam.

(2) During periods of unusually heavy rains, provide round-the-clock surveillance of Meadow Run Dam. Have sufficient personnel available to clear any debris that might collect at the spillway bridge.

(3) When warnings of a storm of major proportions are given by the National Weather Service, the Owner should activate his emergency operation and warning system.

(4) Institute an inspection program at the dam such that the dam is inspected frequently. As presently required by the Commonwealth, the inspection program should include a formal annual inspection by a professional engineer experienced in the design and construction of dams. Utilize the inspection results to determine if remedial measures are necessary.

(5) Institute a maintenance program such that all features of the dam are properly maintained.

PHASE I INSPECTION REPORT

NATIONAL DAM INSPECTION PROGRAM

JUNE 1980

SECTION 1

PROJECT INFORMATION

1.1 General.

a. Authority. The Dam Inspection Act, Public Law 92-367, authorized the Secretary of the Army, through the Corps of Engineers, to initiate a program of inspection of dams throughout the United States.

b. Purpose. The purpose of the inspection is to determine if the dam constitutes a hazard to human life or property.

1.2 Description of Project.

a. Dam and Appurtenances. Meadow Run Dam is a homogeneous earthfill embankment with a timber corewall. The dam is 577 feet long and is 15 feet high at maximum section.

The spillway is located near the right abutment of the dam. It is a 25-foot long broad-crested, concrete weir. The crest is 3.5 feet below the design top of the dam. A concrete deck bridge with steel girders spans the spillway.

The outlet works is located near the center of the embankment. It consists of a 24-inch diameter cast-iron pipe with a gate valve at the downstream end. It is not known if there is an intake structure.

The various features of the dam are shown on the Photographs in Appendix C and on the Plates in Appendix E. A description of the geology is included in Appendix F.

b. Location. Meadow Run Dam is located on Meadow Run in Bear Creek Township, Luzerne County, Pennsylvania, approximately 5 miles northeast of the community of Bear Creek. Meadow Run Dam is shown on USGS Quadrangle, Pleasant View Summit, Pennsylvania, at latitude N 41° 13' 10" and longitude W 75° 40' 05". A location map is shown on Plate E-1.

c. Size Classification. Small (15 feet high, 567 acre-feet).

d. Hazard Classification. High hazard. Downstream conditions indicate that a high hazard classification is warranted for Meadow Run Dam (Paragraphs 3.1e and 5.1c (5)).

e. Ownership. Mrs. Eleanor Taylor, 1360 Jack Road, Monterey, California 93940; c/o Corresponding Agent, Mr. Lee Sweinburg, 589 Wyoming Ave., Wyoming, Pennsylvania 18644.

f. Purpose of Dam. Recreation.

g. Design and Construction History. Meadow Run Dam was originally an ice dam. It was constructed in 1909 under force account for the Bear Creek Ice Company by George Aeslin. The Pennsylvania Water Supply Commission described Mr. Aeslin as "an 'old time' surveyor who furnished the lines and grades during the progress of construction". The dam was originally known as the No. 5 Dam of the Bear Creek Ice Company. The ice company ceased using the dam about 1930; apparently the shores of the lake began to be developed around this time.

A temporary bridge was placed across the spillway at various times by the ice company. By 1965, a timber bridge across the spillway had become a semi-permanent feature of the dam. By this time, the concrete at the spillway was severely deteriorated.

A bridge with a concrete deck and steel girders was constructed in 1978 during the construction of a new spillway, which was of similar dimensions to the old one. The contractor was Charles Malpass and Sons of Forty Fort, Pennsylvania.

h. Normal Operational Procedure. The pool is maintained at the spillway crest level with excess inflow discharging over the spillway. The emergency drawdown facilities are not used. Spillway discharge flows to Mountain Lake Dam, which is immediately downstream.

1.3 Pertinent Data.

a. Drainage Area. (square miles)	1.7
b. Discharge at Damsite. (cfs.)	
Maximum known flood at damsite	Unknown
Outlet works at maximum pool elevation	60
Spillway capacity at maximum pool elevation	
Design conditions	440
Existing conditions	140
c. Elevation. (feet above msl.)	
Top of dam	
Design conditions	2003.6
Existing conditions	2001.7
Maximum pool	
Design conditions	2003.6
Existing conditions	2001.7
Normal pool (spillway crest)	2000.1
Upstream invert outlet works	Not available
Downstream invert outlet works	1986.3
Streambed at toe of dam	1986.3
d. Reservoir Length. (miles)	
Normal pool	0.89
Maximum pool (design)	0.92

e.	Storage. (acre-feet)	
	Normal pool	418
	Maximum pool (design)	754
	Maximum pool (existing)	567
f.	Reservoir Surface. (acres)	
	Normal pool	90
	Maximum pool (design)	102
g.	Dam.	
	Type	Earthfill with timber corewall.
	Length (feet)	577
	Height (feet)	
	Design	17
	Existing	15
	Topwidth (feet)	
	Design	16
	Existing	11
	Side Slopes	
	Upstream	
	Design	1V on 2H
	Existing	Varies, about 1V on 2.8H
	Downstream	
	Design	1V on 2H
	Existing	Varies, about 1V on 1.6H
	Zoning	Corewall.
	Cut-off	Corewall founded in cutoff trench
	Grout Curtain	None.
h.	Diversion and Regulating Tunnel.	None
i.	Spillway.	
	Type.	Broad-crested, concrete weir.
	Length of Weir (feet)	25

i.	Spillway. (Cont'd.) Crest Elevation	2000.1
	Upstream Channel	Reservoir.
	Downstream Channel	Excavated, earthen slope channel parallel to toe of embankment.
j.	Regulating Outlets. Type	One 24-inch dia. CIP.
	Length (feet)	80
	Closure	Gate Valve at downstream end.
	Access	At toe of embankment.

SECTION 2

ENGINEERING DATA

2.1 Design.

a. Data Available. No design data are available for the original dam. In 1915, the Pennsylvania Water Supply Commission (PWSC) prepared a report on the dam. As noted in Paragraph 1.2g, the design was apparently performed as the dam was constructed. All the design data available for the 1978 modifications are shown on Plate E-3 in Appendix E.

b. Design Features. The project is described in Paragraph 1.2a. The various features of the dam are shown on the Photographs in Appendix C and on the Plates in Appendix E.

c. Design Considerations. There is insufficient data to assess the design.

2.2 Construction.

a. Data Available. The only construction data available are reported in the PWSC Report of 1915; an excerpt follows:

> "Prior to the placing of the embankment, the surface material was removed for a depth of from 18 inches to 2 feet, after which selected material was placed in thin layers and compacted by means of the teams and scrapers during the progress of the work. The boulders were thrown out as encountered and afterward used in connection with others in paving both the up and downstream sides of the embankment. Within the embankment there was constructed a cut-off trench, in the bottom of which was placed a concrete base. Extending into this concrete and well up into the embankment was placed a double thickness of timber sheet piling."

b. Construction Considerations. Based on the PWSC data, the construction methods used were adequate.

2.3 Operation. There are no formal records of operation. A record of operation does exist in the form of inspection reports prepared by the Commonwealth between 1920 and 1965.

The previous inspections note maintenance discrepancies, some of which were fairly serious.

2.4 Evaluation.

a. Availability. Engineering data were provided by the Bureau of Dams and Waterway Management, Department of Environmental Resources, Commonwealth of Pennsylvania (PennDER). The Owner made available her agent for information during the visual inspection. Her agent stated that some information was available for the 1978 spillway modifications; the information supplied is shown on Plate E-3.

b. Adequacy. The type and amount of available design data and other engineering data are limited, and the assessment must be based on the combination of available data, visual inspection, performance history, hydrologic assumptions, and hydraulic assumptions.

c. Validity. There is no reason to question the validity of the available data. However, some of the data in the PWSC Report of 1915 is in conflict with the existing data. As there was apparently no design drawing then available to the PWSC, it is surmised that their data was based on rough measurements.

SECTION 3

VISUAL INSPECTION

3.1 Findings.

a. General. The overall appearance of the dam is fair. Deficiencies were observed as noted below. A sketch of the dam with the locations of deficiencies is presented on Exhibit B-1 in Appendix B. Survey information acquired for this Report is summarized in Appendix B. Datum for the survey was taken at a USGS horizontal control point at Mountain Lake Dam, Elevation 1989.0, as shown on USGS mapping. The Owner uses a different datum. To convert the elevations on the Plate E-3 in Appendix E, 1900.9 feet must be added to the elevations on that plate. On the day of the inspection, the pool was 0.2 foot above the spillway crest level.

b. Embankment. The upstream slope of the embankment is covered by sparsely-growing, high brush (Photograph A, B and C). There are some eroded areas on the upstream slope. They are typically 10 to 15 feet long (Photograph C). Parts of the upstream slope above normal pool elevation are near-vertical. The top of the dam is curved in plan, with the part to the left of the outlet works deflecting downstream. Near the point of deflection, which is the highest section of the embankment, there are narrow cracks on the top of the dam that are parallel to the axis of the dam. One 8-foot long crack near the upstream edge of the top and two 3-foot long cracks near the downstream edge were observed. The cracks are hairline in width and their depth could not be probed.

There is a minor surface runoff swale eroded into the downstream edge of the top near the outlet works (Photograph D). The downstream slope is covered with mature trees and brush growing through the stone cover (Photograph E). The downstream slope is uneven, with minor ripples in the stone covering the slope. About 25 feet to the left of the outlet works, the downstream toe is about 6 feet further downstream than at adjacent sections. This appeared to be an as-constructed condition. Tailwater at the dam is caused by Mountain Lake; the upstream end of Mountain Lake is at the toe of the dam (Photograph H). No seepage was observed at the dam.

The survey performed for this inspection reveals that the upstream slope is flatter than the reported design

slope, the downstream slope is steeper than the reported design slope, and the top of the embankment to the left of the spillway is low. The lowest area is at the left abutment and it is 1.9 feet below its design elevation. A section and profile are in Appendix B.

c. Appurtenant Structures. The spillway and spillway bridge are, structurally, in good condition (Photographs F and G). No wingwalls are provided on the structure and the adjacent fill encroaches on the approach channel for 2.5 feet on each side. Two steel I-beams are lying adjacent to the crest. Just downstream of the crest, the spillway walls, which were constructed in 1978, join the remains of the old spillway. The new left wall ends and a short riprap section deflects about 3 feet inward to meet the old spillway wall. The new right wall ends at a short length of earthen slope. The remains of the old spillway extend downstream of the earthen slope. The remains of the old spillway are in very poor condition. Some of the remains are tilting; other parts have wide structural cracks. The channel extends downstream from the spillway in an unprotected earthen channel parallel to the toe of the embankment. There is a minor amount of brush and debris in the channel, which otherwise is in good condition.

The outlet works is in poor condition. The timber frame gate house is capsized downstream of the gate valve (Photograph I). The gate valve itself has a 1.5-foot long crack through the gate housing. The nuts securing the gate housing are so rusted that only a small portion remains. The Owner's agent offered to operate the valve until he discovered that there was no operating mechanism. He did not recall the valve ever being operated.

d. Reservoir Area. The watershed area is mostly wooded, with only an insignificant amount of rural development adjacent to the lake. At the reservoir, the slopes are mild and mostly wooded. There is a beaver dam at the upstream end of the reservoir.

e. Downstream Channel. Immediately downstream of the outlet works and spillway channel is Mountain Lake. A further description is in Section 5.

SECTION 4

OPERATIONAL PROCEDURES

4.1 Procedure. The reservoir is maintained at spillway crest, with excess inflow discharging over the spillway and into Mountain Lake. The emergency drawdown facilities are not used.

4.2 Maintenance of Dam. The dam is visited at irregular intervals, except during the winter, by the Owner's agent. The dam is not visited in winter. The agent, who is a professional engineer and who is related to the Owner, stated that the association between himself and the Owner is informal and uncompensated. He gives verbal reports to the Owner. Formal inspections are not made. Brush was reportedly being cut 2 years ago.

4.3 Maintenance of Operating Facilities. The outlet works is not maintained. It has not been operated recently.

4.4 Warning Systems in Effect. The Owner's agent stated that there is no emergency operation and warning system.

4.5 Evaluation of Operational Adequacy. The maintenance of the dam is inadequate. Inspections are necessary to detect hazardous conditions at the dam. A detailed emergency operation and warning system is necessary to reduce the risk of dam failure should adverse conditions develop and to prevent loss of life should the dam fail.

SECTION 5

HYDROLOGY AND HYDRAULICS

5.1 Evaluation of Features.

a. Design Data. No design data are available for the hydraulics of the original structure. The Pennsylvania Water Supply Commission analyzed the hydraulics as part of their 1915 Report. They used a discharge coefficient of 2.6. A discharge coefficient of 2.7 is used in the analysis described hereafter. The effects of the spillway bridge, which did not exist in 1915, have also been used in the analysis described hereafter. The drainage area of 1.7 square miles that is used in this Report was based on recent USGS mapping. The drainage area of 1.4 square miles that is in the records was probably based on mapping current before 1915.

b. Experience Data. The Owner's agent surmised that Tropical Storm Agnes in June 1972 was the flood of record. There is no pool data to estimate the flow.

c. Visual Observations.

(1) General. The visual inspection of Meadow Run Dam, which is described in Section 3, resulted in a number of observations relevant to hydrology and hydraulics. These observations are evaluated herein for the various features.

(2) Embankment. The low areas on the top of the embankment limit the existing spillway capacity to much less than the design capacity.

(3) Appurtenant Structures. There is no evidence to suggest that the outlet works is operational. There are no upstream closure facilities for the outlet works. The severely-rusted, securing nuts and the cracked gate housing could cause the valve to jam, if it were to be operated. If the outlet works is not operational, there would be no means to draw down the lake in case of an emergency. It is surmised that the timber frame gate house overturned during a strong wind; no means of securing it to the concrete foundation was observed. Even in place, it probably provided only marginal protection against the elements.

The underside of the spillway bridge and the I-beams lying near the crest both have the potential to collect debris. This would reduce the spillway capacity; these effects have not been included in the analysis described hereafter. The effects of the possible pressure flow under the spillway bridge have been included. Although the geometry of the spillway channel immediately downstream of the weir is undesirable because it creates poor flow characteristics, it is estimated that these effects on the spillway capacity would be minor. However, the lack of a wingwall on the upstream side and at the right downstream side of the weir provide an erosion hazard. The deterioration of the remains of the old spillway are not of concern because they are no longer a functional part of the dam. The spillway channel is estimated to be capable of adequately conveying the spillway discharge with the pool at existing top of dam. If the dam were at its design elevation or if the spillway capacity were increased, the spillway channel could overtop and erosion could occur in the channel itself. The brush and debris that is presently in the channel are minor at present but an increase of brush and debris would decrease the conveyance of the channel.

(4) Reservoir Area. The amount of development in the reservoir area is negligible at present. No conditions were observed in the reservoir that might present a hazard to the dam.

(5) Downstream Conditions. A failure of Meadow Run Dam would cause the failure of Mountain Lake Dam, which is immediately downstream. Depending on the rate of dam failure, if Meadow Run Dam failed, it is conceivable that the surge could flood some dwellings along the shore of Mountain Lake. A Phase I National Dam Inspection Program Report is concurrently being prepared for Mountain Lake Dam, which is a small size, high hazard dam with a seriously inadequate spillway capacity. There are 4 dwellings downstream from Mountain Lake Dam that would be flooded by a failure of either Mountain Lake Dam or Meadow Run Dam, with the resulting potential for loss of life. In addition, further downstream is Bear Creek Lake Dam, for which a Phase I Report has previously been prepared. Bear Creek Lake Dam is a small size, high hazard dam with a seriously inadequate spillway. Failure of Meadow Lake Dam could cause the overtopping of Bear Creek Lake Dam. The downstream conditions indicate that a high hazard classification is warranted for Meadow Run Dam.

d. Overtopping Potential.

(1) Spillway Design Flood. According to the criteria established by the Office of the Chief of Engineers (OCE), the Spillway Design Flood (SDF) for the size (Small) and hazard potential (High) of Meadow Run Dam is between 1/2 of the Probable Maximum Flood (PMF) and the PMF. Because of the downstream conditions, the PMF is selected as the SDF for Meadow Run Dam. The watershed was modeled with the HEC-1DB computer program. A description of the model is included in Appendix D. The assessment of hydrology and hydraulics is based on existing conditions, and the effects of future development are not considered.

(2) Summary of Results. Pertinent results are tabulated at the end of Appendix D. The analysis reveals that Meadow Run Dam can pass about 13 percent of the PMF before overtopping of the dam occurs. The dam is rated at its existing top elevation. At its design top elevation, the dam could pass about 35 percent of the PMF.

(3) Spillway Adequacy. The criteria used to rate the spillway adequacy of a dam are described in Appendix D. Because Meadow Run Dam cannot pass the 1/2 PMF, a further analysis was performed. For both the 50 percent and 20 percent PMF, analyses were performed assuming that Meadow Run Dam fails with and without the resulting failure of Mountain Lake Dam. The results indicate that for the 20 percent PMF, even without the failure of Mountain Lake Dam, the stream would rise near the dwellings to a level that is 9.5 feet above the level that would exist if the dam were not to fail. During the 50 percent PMF, the failure of Meadow Run Dam by itself would just overtop Bear Creek Lake Dam, assuming no other inflow to Bear Creek Lake. There is an increased hazard to loss of life; the spillway capacity of Meadow Run Dam is rated as seriously inadequate.

SECTION 6

STRUCTURAL STABILITY

6.1 Evaluation of Structural Stability.

a. Visual Observations.

(1) General. The visual inspection of Meadow Run Dam, which is described in Section 3, resulted in a number of observations relevant to structural stability. These observations are evaluated herein for the various features.

(2) Embankment. The growth of trees and brush on the slopes is a hazard to the dam. Root systems of trees and brush can loosen embankment material, displace slope protection, and create paths along which seepage and piping (internal erosion) might occur.

As noted in Paragraph 2.4c, the record design data may not actually reflect the as-built condition of the dam. Therefore, no particular significance is attached to the variation between the design data and the existing conditions. The variations in the downstream slope and the ripples in the stone cover are not of major concern because they could reflect an as-built condition. The erosion at the top near the downstream edge is caused by poor control of surface runoff. The erosion on the upstream slope is probably caused by waves; this latter erosion was probably exacerbated by the steep upper portion of the slope. Neither condition is particularly serious at present, but further erosion would be a hazard.

Although no seepage was observed at the dam, the upper end of Mountain Lake could have obscured seepage areas. The downstream slope is steeper than normal for a dam of this type. The timber corewall, even if it were in good condition, could not be relied upon to add significant shear strength to the embankment. The cracks on the top of the dam indicate that at least the upper portions of the embankment are slightly separated, thus providing no shear resistance. The depths of the existing cracks, as well as the reason for their development, are unknown. The stability of the existing embankment is considered marginal.

(3) Appurtenant Structures. No structural deficiencies were observed at the spillway. The outlet works is assessed in Section 5.

b. Design and Construction Data. No stability analyses were available for the embankment. The existing conditions are assessed in Paragraph 6.1a.

c. Operating Records. There are no formal records of operation. According to available records, no stability problems have occurred over the operational history of the dam.

d. Post-construction Changes. Post-construction changes are described in Paragraph 1.2g. The modifications to the spillway do not affect the stability of the embankment. Although Plate E-3 does not indicate that a new weir was constructed when the spillway bridge was replaced, the weir appeared to be of recent construction.

e. Seismic Stability. Meadow Run Dam is located in Seismic Zone 1. Earthquake loadings are not considered to be significant for small dams located in Seismic Zone 1 when there are no readily apparent stability problems. However, since the stability of the embankment is deemed marginal, the ability of the embankment to withstand an earthquake is also considered marginal.

SECTION 7

ASSESSMENT, RECOMMENDATIONS, AND PROPOSED REMEDIAL MEASURES

7.1 Dam Assessment.

a. Safety.

(1) Based on available records, visual inspection, calculations, and past operational performance, Meadow Run Dam is judged to be in poor condition. The recommended SDF for the size and hazard category of the dam varies between the 1/2 PMF and the PMF. Based on the criteria and the downstream conditions, the selected SDF at the dam is the PMF. Based on existing conditions, the spillway will pass about 13 percent of the PMF before overtopping of the dam occurs. Failure of the dam would cause an increased hazard to loss of life downstream. If the low area on the top of the embankment were filled to the design elevation, the spillway would pass about 35 percent of the PMF. For either condition, the spillway capacity is rated as seriously inadequate. According to criteria established for these studies, the dam is considered to be unsafe, nonemergency, because the spillway capacity is seriously inadequate.

(2) Because of the nature of its construction, the steep downstream slope, and cracks that have developed on the top of the embankment, the stability of the embankment is considered marginal.

(3) There is no evidence to suggest that the emergency drawdown facility is operational. It is in poor condition.

(4) Maintenance at the dam is inadequate.

(5) A summary of the features and observed deficiencies is listed below:

Feature and Location	Observed Deficiency
Embankment:	Low areas; mature trees and brush on slopes; cracks in top; eroded areas.
Spillway:	Debris near weir; minor debris in spillway channel, erosion potential due to lack of wingwalls.
Outlet Works:	No upstream closure facilities; almost certainly inoperable; cracked casing; severely rusted securing nuts.

b. Adequacy of Information. The information available is such that a preliminary assessment of the condition of the dam can be inferred from the combination of visual inspection, past performance, and computations performed prior to and as part of this study.

c. Urgency. The recommendations in Paragraph 7.2 should be implemented immediately.

d. Necessity for Further Investigations. In order to accomplish some of the remedial measures outlined in Paragraph 7.2, further investigations by the Owner will be required.

7.2 Recommendations and Remedial Measures.

a. The following studies and remedial measures are recommended to be undertaken by the Owner, in approximate order of priority, immediately:

(1) Remove the steel I-beams lying near the spillway weir.

(2) Perform additional studies to more accurately ascertain the spillway capacity required for Meadow Run Dam as well as the nature and extent of measures required to provide adequate spillway capacity. The studies should also assess the need for an improved outlet channel for the existing spillway and the erosion potential at the spillway. Take appropriate action as required.

(3) Perform comprehensive investigations and studies as required to assess the structural stability for the dam. The investigations and studies should address conditions within the dam and foundation. These studies should also address the slope protection required to prevent erosion. The final top of dam elevation should be coordinated with the spillway study recommended above. Until the studies are complete and any necessary remedial action taken, the Owner should monitor the condition of the dam. If any changes occur, immediate remedial action should be taken.

(4) Provide whatever measures are necessary to make the outlet works operational. Once operational, it should be maintained and operated on a regular basis. Also provide an upstream closure facility for the outlet works and assess the need for a structure around the gate valve to protect it from freezing.

(5) Remove trees and brush growing on or near the embankment.

All investigations, studies, designs, and inspection of construction should be performed by a professional engineer experienced in the design and construction of dams. Tree removal should also be guided by a professional engineer.

b. In addition, the Owner should institute the following operational and maintenance procedures:

(1) Develop a detailed emergency operation and warning system for Meadow Run Dam.

(2) During periods of unusually heavy rains, provide round-the-clock surveillance of Meadow Run Dam. Have sufficient personnel available to clear any debris that might collect at the spillway bridge.

(3) When warnings of a storm of major proportions are given by the National Weather Service, the Owner should activate his emergency operation and warning system.

(4) Institute an inspection program at the dam such that the dam is inspected frequently. As presently required by the Commonwealth, the inspection program should include a formal annual inspection by a professional engineer experienced in the design and construction of

dams. Utilize the inspection results to determine if remedial measures are necessary.

(5) Institute a maintenance program such that all features of the dam are properly maintained.

APPENDIX D

HYDROLOGY AND HYDRAULICS

APPENDIX D

HYDROLOGY AND HYDRAULICS

Spillway Capacity Rating:

In the recommended Guidelines for Safety Inspection of Dams, the Department of the Army, Office of the Chief of Engineers (OCE), established criteria for rating the capacity of spillways. The recommended Spillway Design Flood (SDF) for the size (small, intermediate, or large) and hazard potential (low, significant, or high) classification of a dam is selected in accordance with the criteria. The SDF for those dams in the high hazard category varies between one-half of the Probable Maximum Flood (PMF) and the PMF. If the dam and spillway are not capable of passing the SDF without overtopping failure, the spillway capacity is rated as inadequate. If the dam and spillway are capable of passing one-half of the PMF without overtopping failure, or if the dam is not in the high hazard category, the spillway capacity is not rated as seriously inadequate. A spillway capacity is rated as seriously inadequate if all of the following conditions exist:

(a) There is a high hazard to loss of life from large flows downstream of the dam.

(b) Dam failure resulting from overtopping would significantly increase the hazard to loss of life downstream from the dam from that which would exist just before overtopping failure.

(c) The dam and spillway are not capable of passing one-half of the PMF without overtopping failure.

Description of Model:

If the Owner has not developed a PMF for the dam, the watershed is modeled with the HEC-1DB computer program, which was developed by the U.S. Army Corps of Engineers. The HEC-1DB computer program calculates a PMF runoff hydrograph (and percentages thereof) and routes the flows through both reservoirs and stream sections. In addition, it has the capability to simulate an overtopping dam failure. By modifying the rainfall criteria, it is also possible to model the 100-year flood with the program.

APPENDIX D

DETERMINATION OF PMF RAINFALL & UNIT HYDROGRAPH

UNIT HYDROGRAPH DATA:

Sub-area	Drainage Area (square miles)	Cp (1)	Ct (2)	L miles (3)	L_{ca} miles (4)	L' miles (5)	Tp hours (6)	Map Area (7)	Plate (8)
A-1	1.67	0.45	2.1	2.27	.795	N/A	2.51	2	B
Total	1.67								

(See Sketch on Sheet D-4)

(1) & (2): Snyder Unit Hydrograph coefficients supplied by Baltimore District, Corps of Engineers on maps and plates referenced in (7) & (8)

The following are measured from the outlet of the subarea:

(3): Length of main watercourse extended to divide

(4): Length of main watercourse to the centroid

The following is measured from the upstream end of the reservoir at normal pool:

(5): Length of main watercourse extended to divide

(6): $Tp=C_t \times (L \times L_{ca})^{0.3}$, except where the centroid of the subarea is located in the reservoir. Then $Tp=C_t \times (L')^{0.6}$

Initial flow is assumed at 1.5 cfs/sq. mile

Computer Data: QRCSN = -0.05 (5% of peak flow)
RTIOR = 2.0

MEADOW RUN DAM

APPENDIX F

GEOLOGY

Meadow Run Dam is located in Luzerne County within the Appalachian Plateau Physiographic Province. The most pronounced topographic feature in the area is Camelback Mountain, which is part of the Pocono Plateau Escarpment. This escarpment has a well-defined southwestward trend from Camelback Mountain, but is irregular between Camelback Mountain and Mt. Pocono, which lies to the north. Streams east of the escarpment drain directly to the Delaware River, while those to the west drain to the Lehigh River.

The Pocono Plateau Section lies to the west of the escarpment. This area is relatively flat, with local relief seldom exceeding 100 feet. The topography has been greatly influenced by continental glaciation. Many features were created by deposition of glacial materials. The entire plateau lacks well-developed drainage.

East of the escarpment is the Glaciated Low Plateaus Section of the province. This area is characterized by pre-glacial erosional topography with locally-thick, glacial deposits. Local relief is generally 100 to 300 feet.

Bedrock units of the sections described above are the lithified sediments of offshore marine, marginal marine, deltaic, and fluvial environments associated with the Devonian Period. These units include siltstones of the Mahantango Formation, siltstones and shales of the Trimmers Rock Formation, and seven mapped members of the Catskill Formation. These members include sandstones, siltstones, and shales of the Towamensing Member; sandstone, siltstone and shales of the Walcksville Member; sandstones, siltstones and shale of the Beaverdam Run Member; sandstone and shale in the Long Run Member; sandstones and conglomerates in the Packerton Member; sandstone and some conglomerates in the Poplar Gap Member; and sandstones and conglomerates in the Duncannon Member.

Meadow Run Dam is underlain by the Duncannon Member of the Catskill Formation. The Duncannon Member is predominantly a conglomerate and sandstone unit with some

red siltstone and shale. Conglomerates present are generally thick-bedded with subangular to well-rounded quartz pebbles in a coarse-grained sandstone matrix. They are very well indurated and have low porosity due to silica cementation. The sandstones are predominantly fine-to medium-grained, thin-to thick-bedded and well-indurated with a clay and silica cement. Red sandstones near the top of the unit grade into red siltstone and shale, marking the contact with the Spechty Kopf Formation.

The Duncannon Member maintains very steep cut slopes. It is reported to be an excellent foundation for heavy structures. Bedrock is almost entirely overlain by till of Late Wisconsin Age. This till is basically an unsorted mixture of clay, silt, sand, and gravel. It is moderately cohesive and is generally derived locally from the sandstones of the Catskill Formation. Thickness of the till varies from 3 to 100 feet.

Available information, which is scant, indicates that the dam is probably founded on this till.
